#### ABSTRACT

This paper evaluated the effect of auto framing materials to passenger in collisions by Ansys LS-DYNA simulation software and analysis data by Hyperview software. Process simulation helps authors problem research, survey the feasibility of replacing traditional steel materials in the automotive manufacturing industry in Vietnam by carbon fiber composite materials. In addition, the simulation also allows the author to easily change the contact angle, the velocity of impact on a flexible, easy to achieve high economic efficiency during the actual test.

Key words: SAMCO-BT3, Ansys LS-DYNA, Solidworks, Hyperview, Composite carbon fiber

#### **1. INTRODUCTION**

Reduced self-weight of cars and increased passive safety are two important factors when designing automobile frames, shell. During the design process, typically some parts anticollision on cars will be made from synthetic resin to absorb energy. Also partial skeleton structure is also designed to be able to absorb the highest energy is intended to increase the reliability and safety of people and vehicles.

The examination of the anti-collision or safety for people and vehicles are evaluated by analyzing the collision process. Impact assessment process is usually done under the following methods:

- Experiment;
- Simulation the impact of the software.

The first selection method with the accuracy and reliability but high cost and implementation process is extremely complex, so not suitable for the current conditions in Vietnam. The application of simulation software collision between two cars to solve the problems of reliability frame, shell and passive safety has brought high accuracy while reducing costs and time of implementation experience. To gradually develop mandatory standards applied to the passenger car's frame structures design, manufacturing and assembly in Vietnam, including taking into account the requirements for structural strength, the material of the frame, shell self protection when the collision occurs. Therefore in this paper, the authors use the LS-

DYNA ANSYS software and analysis data software on Hyperview to determine the influence of framing materials, to passenger cars bone collisions to determine Bumpers possibility of framing materials, peel through the safety standards of the European people.

## 2. FINITE ELEMENT MODELING AND SAFETY STANDARDS FOR COLLISION

Problem analysis techniques collision dynamics instant by simulation in ANSYS is used to determine the response of structures under the influence of time-dependent loads. We can use this type of analysis to determine the displacements, deformation, stress and timevarying forces. Simulations provide a detailed physical phenomena occurring in the structure of the model since it enables the engineers can adjust the texture before finalizing the design to put into production.

Collision simulation process is performed using software finite element simulation. A finite element model was designed and entered into LS-DYNA ANSYS with the boundary conditions, loads and element type defined conditions close to the actual collision.

#### 2.1 Finite element models

The SAMCO-BT3 and passenger car's frame structures model designed in SolidWorks (Figure 1) \* IGES file is exported, then imported into the software Hypermesh to build finite element. By using the meshing method automesh on each array of car's frame structures (type SHELL element 163), we obtain a finite element model (Figure 2)

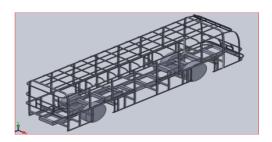

Figure 1. Geometric model passenger car

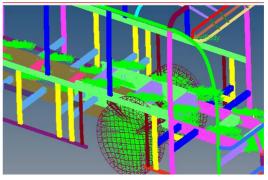

Figure 2. Finite element models

### **2.2 HIC standards, safety SI for human when the collision**

This is the international standard for assessing the safety of passengers when automobile to the force of impact. Under this standard, the limits of tolerance of people is considered a function of time with the maximum impact force. FMVSS 208 safety standards of the US [3] defined as follows [7]:

Standard head injury HIC, limited in 1000:

$$HIC = \left[\frac{1}{t_2 - t_1} \int_{t_1}^{t_2} \frac{b_{head}}{g} dt\right]^{2,5} \cdot (t_2 - t_1)$$

Which: b<sub>head</sub>: the largest accelerator in head;

t: time impact collision.

The HIC limit is 1000, while the HIC from 1500 to 2000, brain severe injury resulting in death

Standard chest injury SI, SI limit is 1000:

$$SI = \int_{0}^{t} \left(\frac{b_{chest}}{g}\right)^{2,5} dt$$

Which: b<sub>chest</sub>: the maximum acceleration in the chest;

t: time impact collision.

This limitation is based on biomechanical studies that chest can withstand 60g acceleration of 3ms without injury, the degree of compression is limited 3inches chest.

#### **3. SIMULATION**

Table 1 The simulation case						
TT	C	Simulation				
	Angle of collision	Speed (V1: car collision,	code			
		V0: collison)				
1	<b>90</b> <sup>0</sup>	$V_1 = 15 \text{ km/h}, V_0 = 0$	M1			
2	90 <sup>0</sup>	$V_1 = 20 \text{ km/h}, V_0 = 10$	M2			
3	$27^{0}$	$V_1 = 20 \text{ km/h}, V_0 = 10$	M3			
4	43 <sup>0</sup>	$V_1 = 48 \text{ km/h}, V_0 = 10$	M4			

The author simulated side collision between the same two cars with the velocity and impact angle different. The SAMCO-BT3 and passenger car's frame structures is CT3 steel material, then replaced respectively by composite materials with similar conditions (table 1) [5]. The load placed on the vehicle model is kinetic energy collision of car collisions  $T = \frac{1}{2}mV^2$  [4], have varying value depending on the method, direction and magnitude of the initial velocity vehicle collisions. The magnitude of the collision velocity decreases from V = V0 (initial velocity) until V = 0 (velocity end collisions) during analysis is 0,1 seconds collision. During this time we divided into 100 steps, so the increment of time is 0,001 seconds. In each step of the program will record the results.

#### 4. RESULTS AND EVALUATION

Simulations in the case in (Table 1) with frame material, frame then replaced with composite materials we obtain the results shown in Section 4.1; 4.2. Some figure collision in case M1, shown in Figure 3, 4

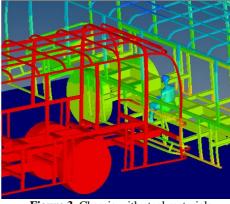

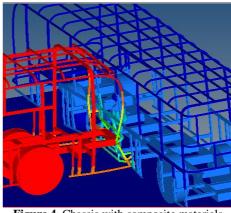

Figure 3. Chassis with steel materials

**Figure 4.** Chassis with composite materials Results of simulation Button 137 681: on top of passenger

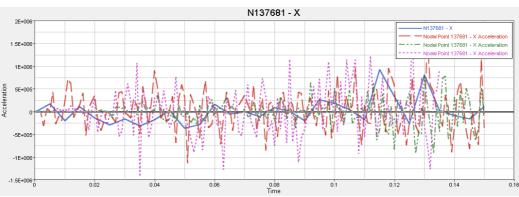

Button 347 278: on the passenger's chest

Button 349 295: on the lap of passengers

The obtained results are as follows:

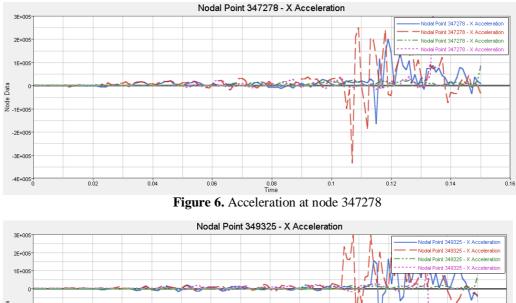

Among them : the blue line graph in case M1

- : red line graph of cases M2
- : green line graph in case M3
- : light purple line graph in case M4

#### 4.1 Acceleration in the survey button when the vehicle using steel materials

#### 4.2 Acceleration in the survey button when car use composite materials

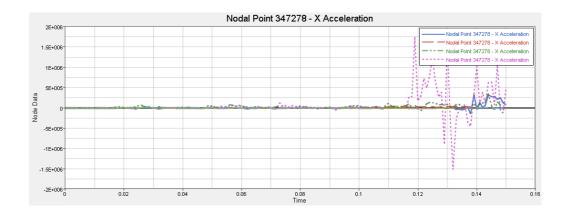

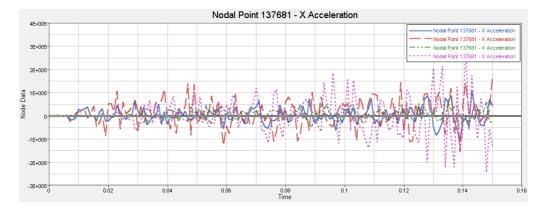

Figure 9. Acceleration at node 347278 composite

Case	Standard HIC		Standard SI	
Materials	Steel	Composite	Steel	Composite
M1	1048.17	788.44	1056.68	869.57
M2	845.33	511.82	684.75	625.83
M3	759.92	378.49	649.55	416.14
M4	3108.22	1063.28	3959.33	1015.64

The results were as standard and standard HIC SI

According to the timeline the collision to passengers using carbon fiber composite materials have greatly reduced compared to vehicles using steel materials.

The impact force is reduced due to the energy absorption of carbon fiber composite materials.

#### 5. CONCLUSION

From the chart we see time acceleration affected passengers collided when replaced with composite materials greatly reduced.

The HIC value standard, SI showed the car using carbon fiber composite materials are always lower than carbon steel materials.

Energy absorption capacity of carbon fiber composite materials is very high so it reduces injury collisions.

From the above results show that use of carbon fiber composite materials in industrial production for passenger cars chassis because it features very good impact reduction.

## Nghiên cứu ảnh hưởng của vật liệu đến kết cấu khung xe con trong trường hợp xảy ra va đâm bằng Ansys LS-DYNA

#### Nguyễn Khắc Huân

#### TÓM TẮT

Bài báo bày đánh giá ảnh hưởng của vật liệu khung xe con trong trường hợp va đâm bằng phần mềm mô phỏng ANSYS LS-DYNA và phân tích dữ liệu bằng Hyperview. Quá trình mô phỏng giúp giải bài toán, khảo sát tính khả thi trong việc thay thế vật liệu thép thông thường sử dụng làm khung ô tô bằng vật liệu sợi carbon composite. Ngoài ra, quá trình mô phỏng cũng cho phép dự đoán sự thay đổi của góc tiếp xúc, vận tốc va chạm phức tạp nhằm đạt hiệu quả kinh tế cao trong quá trình thử nghiệm thực tế.
